So the advantage of Docker is it does not matter what your distro of choice is, everything is hidden in the container.

So I have found as per the other thread qdos-gcc is currently not working on arm, as the last post from @tcat seemed to indicate they had found a fix I have asked for details so I can add it. I still need to test xtc68 on arm.

Just pushed an updated image.

This should bring working arm support for xtc68 and qdos-gcc.

I also added qltools so you can make floppy images inside the container!

Oh and I forgot to say the build/build.sh script in the github repo will also build in local machine if you want to play without docker.

Although it will not handle compiling gcc on a 64bit OS (PRs greatefully received 😄)

And now amd64 (x86_64) containers are included.

ARM64 doesnt support multilib though, so I don't think that will ever get gcc 2.95.3!
